Vision API Endpoints

The Vision Application Programming Interface (API) is a RESTful web service that enables access to Vision data and data products:

Indexed Data Collection

- **SEARCH** endpoint allows for targeted, complex queries with various parameters and filters to retrieve full documents from the entirety of Vision's indexed data collection.
- **RANSOMWARE** endpoint facilitates querying for organization mentions on a selection of Ransomware as a Service (RaaS) websites and blogs from Vision's indexed data collection.
- **DOCUMENT** endpoint allows for retrieval of specific documents from Vision's indexed data collection.

Structured Datasets

- **ENTITY** endpoints allow for lookup of structured records associated with cryptocurrency, emails, IP addresses, or credit cards.

Analytical Products

- **DARKSONAR** endpoint allows for retrieval of a relative risk rating for a domain, which captures rising or falling cyber risk over time. Ratings are based on credential exposure of a domain as seen in Vision's data collection, compared with the domain's baseline.
- **SCORE** endpoints allow for requesting and retrieval of DARKINT score calculations and associated formula inputs. Scores are based on the quality, quantity, and recency of exposed data found in Vision's data collection.

API Type	Endpoint Name	Path	Description
Search	Search	/api/v1/search	Form complex searches to query Vision's DARKINT data. Use various query parameters, filters, and options (full body, snippets, or metadata/non-body fields). Documents that meet your criteria are returned with all metadata fields; full body or snippet detail options are available.
	Document	/api/v1/documents/{id}	Return an individual document from Vision, including all metadata fields.

Ransomware	Ransomware	/api/v1/ransomware	Query DarkOwl Vision’s DARKINT data collection for mentions of various organization attributes on ransomware sites.
Entity	Credit Card Number	/api/v1/entity/ccn	Retrieve mentions of a single credit card number found anywhere in the DarkOwl Vision dataset.
	Cryptocurrency Address	/api/v1/entity/crypto-address	Retrieve mentions of a single cryptocurrency address found anywhere in the DarkOwl Vision dataset. Supported currencies: Bitcoin, Dash, Ethereum, Litecoin, Monero, ZCash.
	Email Address	/api/v1/entity/email-address	Retrieve mentions of a single email address found anywhere in the DarkOwl Vision dataset.
	IP Address	/api/v1/entity/ip-address	Retrieve mentions of a single ip address found anywhere in the DarkOwl Vision dataset. IPv4 and IPv6 addresses are supported.
Entity Set	Bank Identification Number	/api/v1/entity/bin	Retrieve all credit card numbers associated with a 6-digit bank identification number, with cvv and expiration date (if available), found anywhere in the DarkOwl Vision dataset.
	Email Domain	/api/v1/entity/email-domain	Retrieve all email addresses within a particular domain, with password and password type (if available), found anywhere in the DarkOwl Vision dataset.
DarkSonar (Beta)	DarkSonar	/api/v1/sonar	Request and retrieve a synchronous relative risk rating and signal interpretation. Includes an option to include historical ratings and baseline calculations in the response.
Score	Submit	/api/v1/score/submit	Request an asynchronous DARKINT Score calculation.
	Status	/api/v1/score/status?id=	Check the status of a DARKINT Score calculation.
	Result	/api/v1/score/result?id=	Retrieve a DARKINT Score and its associated score formula inputs.

Authentication and Authorization Headers

Example Code: [Visit this Link](#)

API Documentation Section: [Authentication](#)

Two headers must be present in each API request: (1) The current datetime, and (2) Your Authorization header. We'll go over how to format/calculate both of these.

1. The current datetime is formatted in UTC, and should look like this:
Wed, 24 Oct 2019 16:59:00 GMT
2. Your Authorization Header will look something like this:
OWL insertYourPublicKeyHere:ABCcEFgHIJKLmnOPqRStu+123/bbQ=

Step 1: Calculating Your Authorization Header

To create your Authorization Header, you will need the following:

- The current date (as formatted above)
- Your request verb in all caps, which is either 'GET' or 'POST' depending on the endpoint
- The full path of your request after the host. As an example, the highlighted part of the full request below is the part that is needed, *including the / after .com*:

`https://api.darkowl.com//api/v1/endpoint1?aParam1=val1&aParam2=val2`

The procedure is as follows:

1. Concatenate the verb, full path, and date into a single string (*no spaces in between each, no newline character*):
 - a. `stringToSign = verb + full path + date`
2. Run the `StringToSign` through the HMAC-SHA1 algorithm using your private key.
3. Base64 Encode the resulting HMAC hash value.
 - a. The HMAC function needs to return a raw binary result, not a hex string.
 - b. Calculate your HMAC before URL encoding the query string. DarkOwl will decode the encoded URLs prior to authenticating, so an HMAC ran on an encoded URL will result in a security hash mismatch.
4. Add an 'Authorization' header value with the HMAC value and public key in the following format, noting the "OWL" keyword in the header as shown here:

Authorization: OWL yourPublicKeyHere:resultFromStep3

Step 2: Adding the Date

Once your authorization header is completed, add a second header with the datetime, as shown here:

Date: Wed, 24 Oct 2019 16:59:00 GMT

Putting It All Together: The Request

To summarize, each request must have the following headers (**your exact values will vary*):

Date: Wed, 24 Oct 2019 16:59:00 GMT

Authorization: OWL insertYourPublicKeyHere:resultFromStep3

Error Codes

We use typical HTTP response codes for bad requests and authentication issues. If your request generates an error, the response will include a more detailed message about the specific error. If you are unsure about what is causing the error, please contact us at productsupport@darkowl.com.

- **If you receive a 403 response** code, please verify that your traffic is originating from an approved IP address for your organization.
- **If you receive a 401 response** code, please verify that your authentication header is correct. One common thing to check: when you base64 encode the output of your HMAC calculation, be sure that it's base64 encoding the raw binary result, not a hex encoded string of the HMAC output.

Working with the Search Endpoint

Example Code: [Visit this Link](#)

API Documentation Section: [Search](#)

Additional Links: [Search Cheat Sheet](#), [UI to Search API Field Map](#), [API Values](#)

When working with the Search endpoint (/api/v1/search), the 'q' parameter is the primary search field recommended for use with keywords or terms.

Each query parameter is designated as either **q (the Base Search)**, **Filter**, or **Result Option**:

- *Only the q parameter determines the relevancy score* of the documents returned by our database; filters are not used in the calculation of relevancy.
- Filters allow for more targeted, performant searches, as they narrow down a result set.
- Result Options allow you to control the way documents are returned, such as with highlighting (highlight=), sorted (sort=), with pagination (offset=), etc.

The q field

The `q` parameter is the Base Search field and *should be used with all searches*. This field accepts letters, numbers, special characters, and operators. Wildcards are generally allowed, except for leading wildcards.

- **Using Quotations and Parentheses:** Use quotations around multi-word phrases or names to group everything together as one item. Parentheses can be used to form subqueries.
- **Using Booleans:** You can use AND, OR, NOT in this field, for example: hack AND breach.
- **Using Search Operators:** Use search operators when searching for emails, cards, ssns, ips, cryptocurrency in the q field.

q=email:(first.last@company.com OR first@company.com)

q=cryptocurrency:griheoaho3249070

q=drugs AND email:(first.last@company.com OR first@company.com)

- **Exact Searching and Stemming:** DarkOwl Vision supports a process called stemming, which tries to reduce a word to an approximation of its stem or root form. This means that searching will return matches on related forms of a word (hope, hopes, hoped, and hoping may be returned in results when searching for hope), unless you specify otherwise. When you want to search for a specific term, including special characters and punctuation, use the exact: operator to prevent word stemming:

q=exact:hack

- **Using highlight with q:** When you append your query with the highlight parameter (&highlight=true), data you enter in the q parameter will be highlighted in the body field in the response.
- **The q parameter determines relevancy:** The relevancy score – how well the result matches the query submitted – is determined by the content in the q parameter; note that filters are not used in the calculation of relevancy.

Paginating through results (Offset parameter) and Count parameter

A maximum of 20 results are returned per request. The 'offset' parameter allows you to skip a number of results. If your query has more than 20 total documents, use the following to get the 'next' page of results, with a maximum of 5,000* results returned for the same query. *Please see the API documentation for current maximum pagination and offset values.*

- offset=0 will return the first 20 results; this is the default
- offset=20 will return results 21-40
- offset=40 will return results 41-60
- etc

When you're initially developing and debugging, you can ask the Search API to return fewer than the default 20 results. The *count* parameter accepts numbers between 1 and 20.

- **When using a count other than the default (20), you may need to adjust your offset.** For example, if you set your count to 2 (count=2) while developing, you would use offset=0 to return the first 2 results, offset=2 to return results 3-4, offset=4 to return results 5-6, and so on.

De-duplicating results (Similar parameter)

You can ask for your documents to be de-duplicated by the Search API, on a per request basis.

- **When this option is selected, you may receive fewer documents** than the count submitted, since some of the results may not be returned. You will receive the number of results actually sent in the *resultCount* in the response.

Leaks available in Vision (Leak parameter)

The leak parameter can be used to filter your search to (or exclude from) known public leaks or database dumps. The values of leaks available through Search API are found here.

Description of Response Fields in Search API

Response fields	Field descriptions
id	The DarkOwl Vision identifier for the result.
body	The full text collected from the webpage/record/target. Note that this field will not be returned if <i>detail=snippet</i> or <i>detail=nonbody</i> is selected in the request.
snippet	Excerpt of the body, based on the first highlighted term in the body. This field will not be returned if <i>detail=body</i> or <i>detail=nonbody</i> is selected in the request, or if the request does not include a detail parameter (the detail default is body).
hackishness	Rating assigned by DarkOwl Vision, indicating the likelihood to which the information could be used for criminal activity. Assigned on a per-page basis.
title	If available, page title of the content collected.
url	URL or location of the content collected.
crawlDate	Date when DarkOwl Vision collected the content.
fileSize	The size of the content before normalization, in bytes.
domain	Domain of the content collected.
ips	A list of ip addresses found in the body, if available.
emails	A list of emails found in the body, if available.
ssns	A list of social security numbers found in the body, if available.
ccns	A list of credit card numbers found in the body, if available.
cryptos	A list of cryptocurrencies found in the body, if available.
cves	A list of Common Vulnerabilities and Exposures found in the body, if available.
headers	The httpHeader content collected with the result, if available.
leak	Leak information and metadata, if the document was sourced from a leak. May include the following fields, if available: <i>name</i> , <i>actors</i> , <i>host</i> , <i>associations</i> , <i>downloadLocations</i> , <i>filepath</i> , <i>filename</i>
chat	Chat information and metadata, if the document was sourced from a chat network. May include the following fields, if available: <i>users</i> , <i>channel</i> , <i>server</i>

Working with the Ransomware Endpoint

API Documentation Section: [Ransomware](#)

The Ransomware endpoint allows you query for organization mentions or other attributes, filtered to a selection of Ransomware as a Service (RaaS) websites and blogs.

Base Search Fields

- At least one Base Search field (see table below) must be used with all searches.
- Base search fields accept letters, numbers, special characters, and operators. Wildcards are generally allowed, except for leading wildcards.
- Up to 10 Base Search fields can be used in a single query.

Base Search Fields	Example	Description
org_name	Mega Corp	Use to look for mentions of an organization's name.
org_domain	megacorp.net	Use to look for mentions of an organization's domain or URLs containing the organization's domain. Be sure to specify the domain portion only (i.e. megacorp.com) and not a full URL (i.e. https://megacorp[dot]com).
contact_name	Cecilia Young	A first and last name. Use to look for mentions of a CEO or key executives mentioned on ransomware sites.
keyword	bitcoin	This field supports either a word or a phrase. Phrases do not need to be in quotations.

Paginating through results (Offset parameter) and Count parameter

A maximum of 20 results are returned per request. The 'offset' parameter allows you to skip a number of results. If your query has more than 20 total documents, use the following to get the 'next' page of results, with a maximum of 5,000* results returned for the same query. *Please see the API documentation for current maximum pagination and offset values.*

- offset=0 will return the first 20 results; this is the default
- offset=20 will return results 21-40
- offset=40 will return results 41-60
- etc

When you're initially developing and debugging, you can ask the Ransomware API to return fewer than the default 20 results. The *count* parameter accepts numbers between 1 and 20.

- **When using a count other than the default (20), you may need to adjust your offset.** For example, if you set your count to 2 (*count=2*) while developing, you would use *offset=0* to return the first 2 results, *offset=2* to return results 3-4, *offset=4* to return results 5-6, and so on.

De-duplicating results (Similar parameter)

You can ask for your documents to be de-duplicated by the Ransomware API, per request. Note that if you select this option, you may receive fewer documents than the count selected, since some of the results may not be returned. You will receive the number of results actually sent in the *resultCount* in the response.

Response Fields in Ransomware API

The response fields are the same as Search API. Please refer to [the table on page 9](#) for detailed descriptions of each field.

Working with the Entity Endpoints

Example Code: [Visit this Link](#)

API Documentation Section: [Entity](#), [Entity Set](#)

Additional Links: [API Values](#)

The Entity endpoints allow you to retrieve structured records relating to four tokenized values identified in our data collection—*emails, IP addresses, cryptocurrency, or credit cards*.

- There are four (4) Entity endpoints that allow you to look up and return records related to an individual or singular **credit card number, cryptocurrency address, email address, or IP address**.
- There are two (2) Entity endpoints that allow you to look up and return records related to a set of email addresses (belonging to one **email domain**) or a set of credit cards (belonging to one **bank identification number (BIN)**).

Supported Entity Inputs

Cryptocurrency Address	Bitcoin, Dash, Ethereum, Litecoin, Monero, ZCash
IP Address	IPv4 addresses, IPv6 addresses
Bank Identification Number	6- or 8-digit Bank Information Numbers

Entity Request Options

Entity types have several common request options, including sort and date range (from/to) options. Certain Entity types may also have unique request parameters, as shown below.

Entity	Unique Request Parameter	Description
Email Domain	leak	Use this parameter to only return content from one specific data leak.

Entity Response Fields

All Entity types have common response options, including id, crawlDate, location, fragment, and network. Certain Entity types may also return unique options, as shown in the table below. If these fields are not returned, it means that field was not detected with the Entity.

Entity	Unique Response	Description
Email Address	password	An associated password that Vision detected with the email address.
Email Address	type	The type of password that Vision detected with the email address (plain, hashed).
Email Domain	password	An associated password that Vision detected with the email address.
Email Domain	type	The type of password that Vision detected with the email address (plain, hashed).
Email Domain	leak	The name of the data leak in which the result was found (if from data leak).
Credit Card Number	cvv	An associated cvv that Vision detected with the credit card number.
Credit Card Number	expDate	An associated expiration date that Vision detected with the credit card number.
Bank Identification Number	cvv	An associated cvv that Vision detected with the credit card number.
Bank Identification Number	expDate	An associated expiration date that Vision detected with the credit card number.

Working with the DarkSonar (Beta) Endpoint

API Documentation Section: [DarkSonar \(Beta\)](#)

Additional Links: [Cyber Risk Modeling: Introducing DarkSonar](#)

DarkSonar is a risk metric based on darknet intelligence and measures an organization's credential exposure on the darknet. It is a relative risk rating that considers the nature, extent and severity of credential leakage on the darknet to provide a company with a signal that acts as a measurement for a company's exposure.

The DarkSonar endpoint allows you to retrieve a relative risk rating for a domain, which captures rising or falling cyber risk over time. The rating is based on email exposure using three parts of email entities: *unique plaintext credentials*, *unique hashed credentials*, and *total unique email address volume with no credentials*.

DarkSonar Request Options

When working with the DarkSonar endpoint, the **domain** parameter is the primary field used, along with the **detail** parameter.

- *detail=rating* will return the current rating (numerical value) and its risk interpretation signal (low, elevated, severe).
- *detail=full* will return the above, plus an array of historical monthly baseline details for the past 24 months. These baseline details are the underlying values upon which the current rating and signal are determined. We recommend graphing these values on a timeline for visualizing purposes.

DarkSonar Response Fields

Response fields	Field descriptions
rating	The z-score for the domain, which is calculated based on the past 24 months of baseline ratings for the domain. The z-score indicates the number of standard deviations away from the mean at this point in time. A DarkSonar rating that is trending upwards away from the mean, or over 1 standard deviation from the mean, can be an early warning sign of risk.
signal	Interpretation of the rating, based on its proximity to the baseline rating. <i>Note these are suggested interpretations and are based on the number of standard deviations away from the mean.</i> <ul style="list-style-type: none"> • Ratings lower than 1 will be considered low. • Ratings equal to or higher than 1 but less than 2 will be considered elevated.

	<ul style="list-style-type: none"> • Ratings equal to or higher than 2 will be considered severe.
date	Date the current rating and signal were calculated.
details	<p>This is a list of objectives outlining monthly historical numbers for this domain, over the past 24 months. It will be an array that includes:</p> <ul style="list-style-type: none"> • date: date at which this baseline and z-score rating were calculated. • baseline: the baseline rating, which is measured by credential exposure on the darknet, with considerations for age and uniqueness. • rating: The z-score for the domain, which is calculated based on the past 24 months of baseline ratings for the domain. The z-score indicates the number of standard deviations away from the mean at this point in time.

Working with the Score Endpoints

Example Code: [Visit this Link](#)

API Documentation Section: [Score](#)

Additional Links: [Guide with Score Formula](#)

The Submit, Status, and Result endpoints work in tandem to perform an end-to-end score calculation and retrieval. The DARKINT Score formula focuses on specific DARKINT sources for unique matches on an organization's website and email domains, and adjusts the results based on hackishness. Inputs include one or more domain(s) and emailDomain(s).

Score Response Fields

The response includes the score, the number of document matches for the domain and emailDomain inputs provided, and the calculated hackishness values.

Response fields	Field descriptions
score	Calculated score, based on the DARKINT Exposure Score formula .
domainPaste	Number of document matches from Paste sources that include domain input value(s).
domainDark	Number of document matches on Darknet sources that include domain input value(s).
domainBreach	Number of document matches within Data Leaks that include domain input value(s).
emailPaste	Number of document matches on Paste sources that include email input value(s).
emailDark	Number of document matches on Darknet sources that include email input value(s).
emailBreach	Number of document matches within Data Leaks that include email input value(s).
hackishness DarkPaste	Average hackishness value of document matches on Paste and Darknet sources that include domain or email input value(s), occurring within the last 90 days.
hackishness Breach	Average hackishness value of document matches within Data Leaks that include domain or email input value(s), over all time.
